# Data Mining & Predictive Modelling Assignment

## Pablo Benayas Penas

## 23/02/2020

- These are the different sections I am going to cover in this assignment:
  - · Firstly, I am going to work with data from the Spanish National Elections. I will clean the dataset and then, will create linear and logistic regression models to predict varaibles thereof.
  - Secondly, Time Series Analysis will be conducted with US\_monthly\_unemployment\_rate data from 2007-08 to present
  - Finally, it will carry out clustering analysis with the aforementioned Spanish National Elections Dataset.

#### PART I To begin with, let's clean the dataset:

```

```

I set less than 10 unique values as benchmark for factor conversion

for the sake of file length, dfplot() is not going to be displayed

```
# function provided by my teacher
#dfplot <- function(data.frame) {
# df <- data.frame
# ln <- length(names(data.frame))
# for(i in 1:ln) {
# if(is.factor(df[,i])) {
# plot(df[,i],main=names(df)[i]) } # 'main' argument: an overall title for the plot
# # names(df)[i] returns its column name
# else(hist(df[,i],main=names(df)[i])
# boxplot(df[,i],main=names(df)[i]) }
# }
#dfplot(elec)</pre>
```

#### Let's check the structure of the dataset

```
str(elec)
```

```
## 'data.frame': 8119 obs. of 41 variables:

# 4) 'Density' has '?' values. Convert them to NAs
elec$Density=as.factor(ifelse(elec$Density=='?', NA, elec$Density))
```

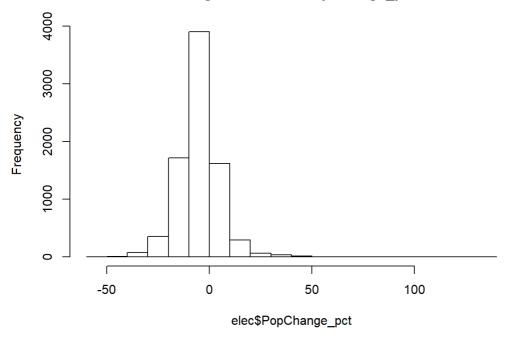

We have to pay special attention to outliers in this dataset. This is because some outliers are completely valid. For example, looking at the 'Population' variable there are two clear outliers ('Madrid and Barcelona') that should be included in the analysis. However, I cannot find any reasonable argument justifying a 138.46% population change in one year. Thus, we are going to modify those values.

IMPORTANT: We are not going to convert continuous variables to categorical. This is because we have several continuous variables and factorization will dramatically increase computational costs for 'lm' and 'glm' models. The main drawback of keeping continuous variables is that we might miss out non-linear relationships in our data.

Later on, we will see that it is possible to fix this problem by conducting mathematical transformations (e.g., x^2, log(x), ...) in our continuous variables. By this way, linearity might be created with the target variable

#### **LINEAR MODELS**

LET'S DEFINE A BINARY TARGET VARIABLE FOR LOGISTIC REGRESSION AND CONTINUOUS TARGET VARIABLE FOR LINEAR REGRESSION

BINARY -> Right wing CONTINUOUS -> AbstentionPtge

Let's get rid of the other potential target variables that we are not going to use We are going to remove 'Name' since each observation has a unique name.

```

#### IMPORTANT: there are collinearity issues in both unemployment and industry variables:

```
# In order to avoid collinearity, We just have to remove one of the variables.

total_lm=total_lm[, !(names(total_lm) %in% c('UnemployMore40_Ptge','AgricultureUnemploymentPtge'))]

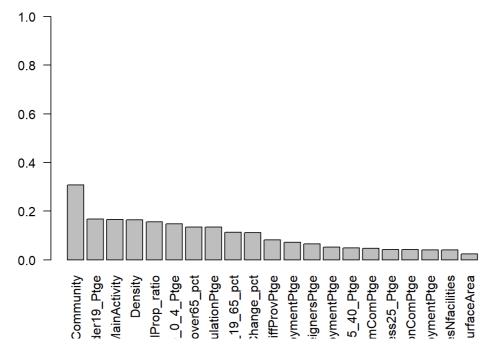

total_lm[1:2, 14:20] #Let's make sure they have been successfully removed
```

Significance of variables

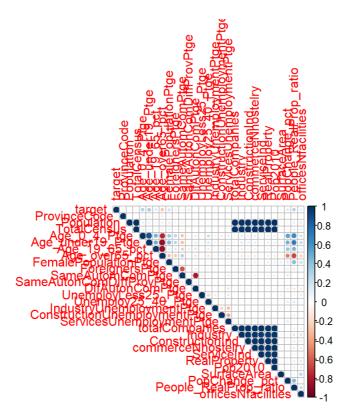

```
# functions provided by my teacher
Vcramer<-function(v, target) {
    if (is.numeric(v)) {
        v<-cut(v,5)
    }
    if (is.numeric(target)) {
        target<-cut(target,5)
    }
    cramer.v(table(v, target))
}

VcramerGraph<-function(matrix, target) {
    outputVcramer<-sapply(matrix, function(x) Vcramer(x, target))
    barplot(sort(outputVcramer, decreasing =T), las=2, ylim=c(0,1))
}

VcramerGraph(total_lm[,3:ncol(total_lm)], total_lm$AbstentionPtge)</pre>
```

correlation among variables (only for numeric ones)

IMPORTANT: We have not converted continuous variables to categorical. This is because we have several continuous variables and factorization will dramatically increase computational costs for 'lm' and 'glm' models. The main drawback of keeping variables continuous is that we might miss out non-linear relationships in our data. It is possible to fix this problem by conducting mathematical transformations (e.g.,  $x^2$ ,  $\log(x)$ , ...) in our continuous variables. This is exactly what it is done in the following lines of code:

```
# function provided by my teacher
bestTransfCorr<-function(vv,target) {
    vv<-scale(vv)
    vv<-vv+abs(min(vv,na.rm=T))*1.0001
    posiblesTransf<-data.frame(x=vv,logx=log(vv),expx=exp(vv),sqrx=vv^2,sqrtx=sqrt(vv),cuartax=vv^4,raiz4=vv^(
1/4))
    return(list(colnames(posiblesTransf)[which.max(abs(cor(target,posiblesTransf, use="complete.obs")))],posib
lesTransf[,which.max(abs(cor(target,posiblesTransf, use="complete.obs")))]))
}
only_numeric_vars=total_lm[,as.vector(sapply(total_lm, function(x) is.numeric(x))) & (!(names(total_lm) %in%
'AbstentionPtge'))]
transformed_total_lm=total_lm
transformed_total_lm[,as.vector(sapply(transformed_total_lm, function(x) is.numeric(x))) & (!(names(transformed_total_lm) %in% 'AbstentionPtge'))] =
    sapply(only_numeric_vars, function(x) bestTransfCorr(x,total_lm$AbstentionPtge)[[2]])
head(transformed_total_lm,2)</pre>
```

```

Let's check how useful these mathematical transformations have been. To do so, R\_square of both normal and transformed variables will be evaluated. 'transformed\_data' will be used from now on

```
# MY FIRST MODEL
# Function provided by my teacher
Rsq<-function(model, target, data) {
  testpredicted<-predict(model, data)
  testReal<-data[, target]
  sse <- sum((testpredicted - testReal) ^ 2)
  sst <- sum((testReal - mean(testReal)) ^ 2)
  1 - sse/sst
}
modell=lm(total_lm$AbstentionPtge ~ ., total_lm)
paste('R_sq_normal_data', round(Rsq(model1,'AbstentionPtge', total_lm), digits=3), '%')</pre>
```

```
## [1] "R_sq_normal_data 0.382 %"
```

```
## [1] "R_sq_transformed_data 0.403 %"
```

#### Let's create all possible combinations of variables

```
# function provided by teacher
#It generates all possible interactions
{\tt varInteractions < -} {\tt function} \, ({\tt data,position}) \, \{ \ \textit{\#position refers to index where target var is } \\
  list of factors<-c()
  list of interactions<-paste(names(data)[position],'~')
  names<-names(data)
  for (i in (1:length(names))[-position]){
    list_of_interactions<-paste(list_of_interactions, names[i],'+')</pre>
    if (class(data[,i]) == "factor") {
      list of factors<-c(list of factors,i)
      for (j in ((1:length(names))[-c(position, list_of_factors)])){
        list_of_interactions<-paste(list_of_interactions, names[i], ':', names[j], '+')</pre>
    }
  }
  list_of_interactions<-substr(list_of_interactions, 1, nchar(list_of_interactions)-1)</pre>
  list of interactions
transformed_interactions=varInteractions(transformed_total_lm, 1)
```

#### Let's check R\_sq of model including all possible interactions

```
# summary(lm(transformed_interactions, data_train))
Rsq(lm(transformed_interactions, transformed_total_lm), 'AbstentionPtge', transformed_total_lm) # a little b
it better
```

```
## [1] 0.4392983
```

## This model only includes the most significant variables with no interactions

```
handmadeModel=lm(AbstentionPtge ~ Autonomous_Community + TotalCensus + FemalePopulationPtge + SameAutomComPt

```

Distance is going to measured by the Euclidean method It is worth mentionning that if Euclidean distance is chosen, then observations with high values of features will be clustered together. The same holds true for observations with low values of features. If we want to identify clusters of observations with the same overall profiles regardless of their magnitudes, then we should go with correlation-based distance as a dissimilarity measure.

```
distance=dist(z, method='euclidean')
print(distance, digits=3)
```

```

## Withing group SS (elbow) method and Silhouette method

```
set.seed(123)
# Scree Plot
z=as.data.frame(z)
wss=(nrow(z)-1)*sum(apply(z,2,var))

# for (i in 1:(nrow(z)-1)) wss[i] = sum(kmeans(z, centers=i)$withinss)
# plot(1:(nrow(z)-1),wss, type='b',xlab='Number of Clusters',
# ylab='Within group SS', main='Handmade Elbow method')

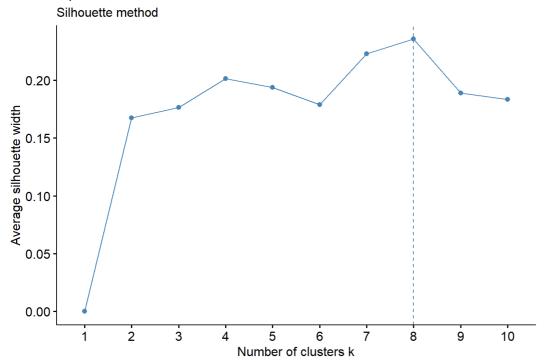

for (i in 1:10) wss[i] = sum(kmeans(z, centers=i)$withinss) #maximum number of clusters created:10
plot(1:10,wss, type='b',xlab='Number of Clusters',
    ylab='Within group SS', main='Handmade Elbow method')
```

# **Handmade Elbow method**

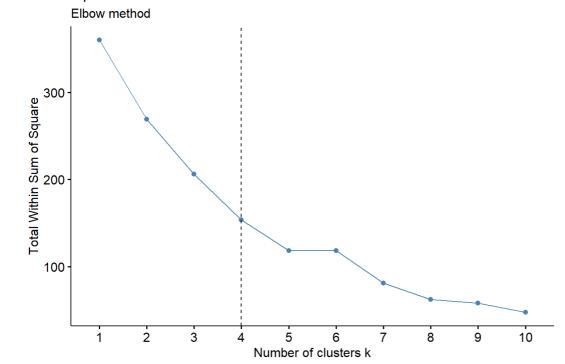

```
fviz_nbclust(z, kmeans, method = "silhouette")+
labs(subtitle = "Silhouette method")
```

# Optimal number of clusters

```
fviz_nbclust(z, kmeans, method = "wss") +
geom_vline(xintercept = 4, linetype = 2)+
labs(subtitle = "Elbow method")
```

# Optimal number of clusters

I SELECT K=4 BECAUSE IT IS THE BEST VALUE ACCORDING TO THE 'ELBOW METHOD'. ADDITIONALY, K=4 HAS THE GREATEST AVERAGE SILHOUETTE WIDTH FOR THE FIRST 6 'number of clusters k'. It is worth mentioning that there are less than 20 observations and, consequently, we are not interested in creating many groups. LET'S IDENTIFY THE MOST SUITABLE LINKAGE METHOD

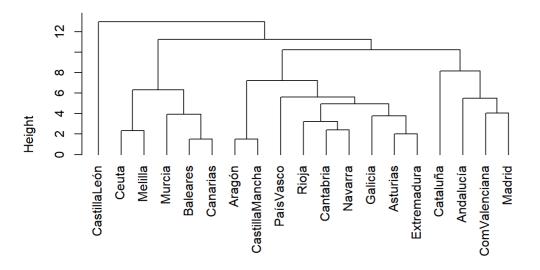

```

## [1] "PCA_random_Kmeans_withinss_mean: 5.453"
```

**FACTOR ANALYSIS** In Factor Analysis, variables are grouped by their correlations, this implies that all variables in a particular group will have a high correlation among themselves, but a low correlation with variables of other group(s). Here, each group is known as a factor. These factors are small in number as compared to the original dimensions of the data. However, it is important to highlight that these factors are difficult to observe and interpret.
